Introduction to Machine Learning Applications

Spring 2020

Lecture-3

Lydia Manikonda

manikl@rpi.edu

Today's agenda

- Python Basics Recap and Loops, Conditionals, Functions
- Including class exercises

Recap on Basics

- Python variables
- Data structures
 - List
 - Dictionary
 - Tuple
 - Set
- Mini class exercise

Mini Quiz

- 1. Suppose list1 is [3, 4, 5, 20, 5, 25, 1, 3], what is list1 after list1.pop(1)?
- 2. Given a string (Example: "machinElearning") count the number of vowels present in the string.

Python fundamentals

Loops, conditionals, functions

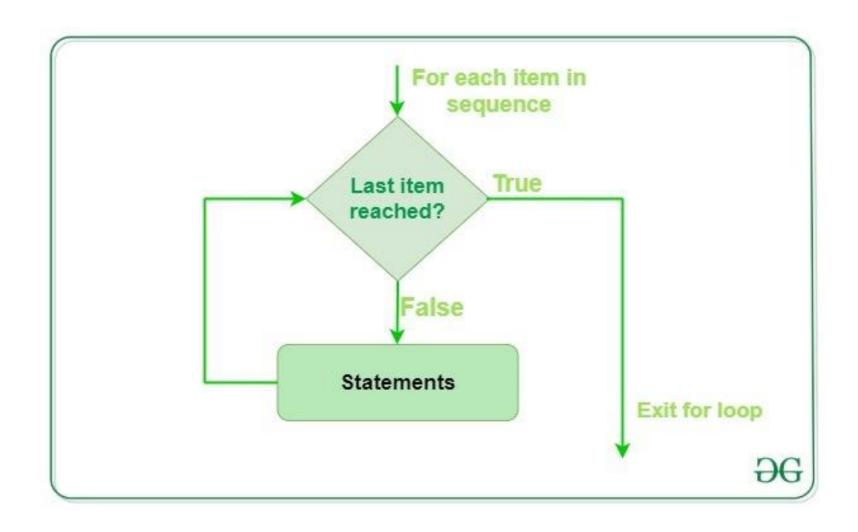

Loops

Loops in Python

```
For While
```

for iterator_var in sequence: while expression: statements(s) statement(s)

for

for

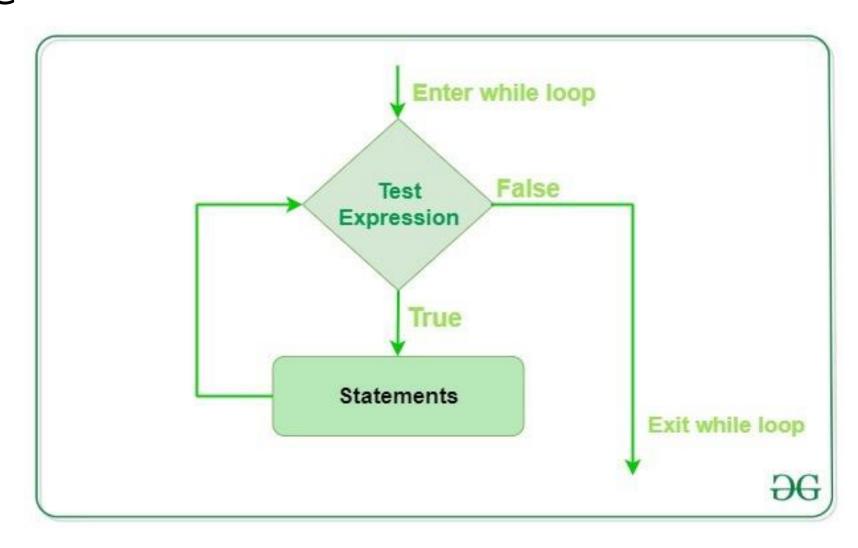

```
>> print("List Iteration")
>> list1 = ["hello", "world"]
>> for i in list1:
         print(i)
>> for i in range(0,10,1):
         print(i)
>> for letter in 'predictiveanalytics': if letter == 'e' or letter == 's':
                   continue
         print('Current Letter :', letter)
```

for loop -- Example

Using the *for* loop print a new list as an output with all the squares of the elements in a given list [1, 2, 3, 4, 5].

Output: [1, 4, 9, 16, 25]

while

while

```
>> count = 0
>> while (count < 3):
        count = count + 1
        print("Hello world!")</pre>
```

While

```
>> i = 0
>> a = 'machinelearning'
>> while i < len(a):
       if a[i] == 'e' or a[i] == 's':
              i += 1
              continue
       print('Current Letter :', a[i])
       i += 1
```

while loop – Example

Write a program to print this format when given a string str1="machine" using while loop:

machine machin machi mach mac

ma

m

Conditionals

If condition

```
if condition:
    statement1
    statement2
# Statements to execute if condition is true
```

if condition:
 statement1
statement2
Here if the condition is true, if block will consider only statement1

Example

```
i = 10
if (i > 15):
        print ("10 is less than 15")
print ("I am Not in if")
```

If-else

```
if (condition):
    # Executes this block if condition is true
else:
    # Executes this block if condition is false
```

Example

```
i = 20
if (i < 15):
       print ("i is smaller than 15")
       print ("i'm in if Block")
else:
       print ("i is greater than 15")
       print ("i'm in else Block")
print ("i'm not in if and not in else Block")
```

If-elif-else

```
if (condition):
    statement
elif (condition):
    statement
...
else:
    statement
```

if-else-if

```
>> num1 = 4
>> if(num1%2 == 0):
      print("Num1 is even")
>> elif(num1%2==1):
      print("Num1 is odd")
>> else:
      print("It never comes to this section")
```

Class Exercise

Given a list I1= [1,2,3,4,5,6,7,8,9,10], print the maximum value till a given index using a *for* loop and *if* statement.

Output: [1,2,3,4,5,6,7,8,9,10]

Functions

Functions

• Set of statements that take inputs and perform certain computations

```
>> def FindEven( x ):
    if (x % 2 == 0):
        print "even"
    else:
        print "odd"
>> FindEven (2)
>> FindEven (3)
```

Functions Example

```
def myFun(x):
     x[0] = 20

lst = [10, 11, 12, 13, 14, 15]
myFun(lst)
print(lst)
```

Pass by Reference

 When we pass a reference and change the received reference to something else, the connection between passed and received parameter is broken.

Pass by Reference – Example-1

Pass by Reference – Example-2

```
def myFunc(x):
     x = 20
x = 10
myFunc(x)
print(x)
```

Pass by Reference

```
def swap(x, y):
       temp = x;
       x = y;
       y = temp;
# Driver code
x = 2
y = 3
swap(x, y)
print(x)
print(y)
```

Default Arguments

Keyword arguments

```
def student(firstname, lastname):
    print(firstname, lastname)
```

```
student(firstname ='John', lastname ='Smith')
student(lastname ='Smith', firstname ='John')
```

Variable length Arguments

Lambda Functions – Anonymous functions

lambda arguments: expression

Example – Intersection of 2 lists

```
>> def ArrIntersect(a1, a2):
    result = list(filter(lambda x: x in a1, a2))
    print ("Intersection : ",result)

>> arr1 = [1, 3, 4, 5, 7]
>> arr2 = [2, 3, 5, 6]
>> ArrIntersect (arr1,arr2)
```

Class exercises

Python notebook

Numpy

Numpy

Fundamental package for scientific computing

- Numpy is a general-purpose array-processing package
- Used for high-performance multidimensional array computations

- A numpy array is a grid of values, all values are of same type
- The number of dimensions is the rank of an array
- A tuple of integers giving the size of an array along each dimension is called the shape of an array

- Initialize using nested python lists
- Access using square brackets

• Declaring the package import numpy as np

- Creating an array of rank 1arr = np.array([1, 2, 3])
- Creating an array of rank 2 arr = np.array([1, 2, 3], [4, 5, 6])

- Create an array with rank 1
- >> a = np.array([1, 2, 3])
- Print the shape of this array
- >> print(a.shape)
- >> (3,)
- Print the elements at different indices
- >> print(a[0], a[1], a[2])

- Change an element of the array
- >> a[0] = 10
- Print the array
- >> print(a)
- >> [10, 2, 3]

```
>> a = np.array([[1, 2, 3, 4], [5, 6, 7, 8], [9, 10, 11, 12], [13, 14, 15, 16]])
>> print(a)
```

Using slicing method printing a range of array

```
>> sliced_a = a[:2, ::2]
```

>> print(sliced_a)

Printing elements at specific indices

>> print(a[[1, 2, 1, 3], [1, 0, 2, 3]])

Numpy – Arrays and Functions

>> [[7. 7.], [7. 7.]]

```
>> a = np.zeros((2, 2))
                                    >> d = np.eye(2)
                                    >> print(d)
>> print(a)
>> [[0. 0.], [0. 0.]]
                                    >> [[1. 0.], [0. 1.]]
>> b = np.ones((1, 2))
                                    >> e = np.random.random((2, 2))
>> print(b)
                                    >> print(e)
>> [[1. 1.]]
                                    >> [[], []]
>> c = np.full((2,2), 7)
>> print(c)
```

 Datatypes of arrays need not be defined – numpy tries to guess the datatype

```
>> a = np.array([1.1, 2.2])
```

>> print(a.dtype)

```
>> a = np.array([1, 2], dtype=np.int64)
```

>> print(a.dtype)

Numpy – Math operations

```
>> a = np.array([[1, 2], [3, 4]], dtype=np.float64)
>> b = np.array([[4, 3], [2, 1]], dtype=np.float64)
>> sum_ab = np.add(a, b)
>> print(sum_ab)
>> sum_a = np.sum(a)
>> print(sum_a)
>> sqrt_a = np.sqrt(a)
>> print(sqrt_a)
>> trans_a = a.T
>> print(trans_a)
```

Numpy Exercises
